

MRI ANKLE - LEFT (WITHOUT CONTRAST)

CLINICAL HISTORY: 39-year-old male, high-energy fall from height, severe ankle pain and deformity.

TECHNIQUE: Multiplanar, multisequence MRI of the left ankle was performed without intravenous contrast.

FINDINGS:

There is a displaced fracture of the distal fibula with associated severe bone marrow edema and disruption of the syndesmotic ligaments (anterior inferior tibiofibular ligament torn).

Deltoid ligament complex shows high-grade sprain with partial tear.

Talar dome shows a small osteochondral lesion with adjacent marrow edema.

Moderate joint effusion.

IMPRESSION:

1. Displaced distal fibular fracture with syndesmotic ligament disruption - high-grade, unstable ankle injury.
2. High-grade deltoid ligament sprain with partial tear.
3. Small talar dome osteochondral lesion.
